Model

The **inputs** are the real, continuous variable z_x , which standardises the increasing attempt numbers, x, of each individual and the dichotomous variable K_i which indicates whether the individual is a kid:

$$z_x = \frac{x - \bar{x}}{\hat{\sigma}_x},$$
 $K_j = \begin{cases} 1 & \text{if } j \text{ is a kid} \\ 0 & \text{else} \end{cases}$ (1)

where \bar{x} is the sample mean and $\hat{\sigma}_x$ the sample standard deviation of x.

The **outputs** are the reaction times, y_j , for each individual j, given the inputs. For our model, we use the $\log(y_j)$ and work with standardised values, $z_{\log(y_j)}$:

$$z_{\log(y_j)} = \frac{\log(y_j) - \overline{\log(y_j)}}{\hat{\sigma}_{\log(y_j)}}$$
 (2)

The applied Bayesian **hierarchical model** expresses the probability of the output given the input and 9 parameters by redistributing the probability proportions as follows:

$$\begin{split} P(z_x, K_j, &\theta_{0_j}, \theta_{1_j}, \sigma, \mu_0, \varphi_0, \mu_1, \varphi_1, \tau_0, \tau_1 | z_{\log(y_j)}) \\ &\propto P(z_{\log(y_j)} | z_x, K_j, \theta_{0_j}, \theta_{1_j}, \sigma, \mu_0, \varphi_0, \mu_1, \varphi_1, \tau_0, \tau_1) \cdot P(\theta_{0_j}, \theta_{1_j}, \sigma, \mu_0, \varphi_0, \mu_1, \varphi_1, \tau_0, \tau_1) \\ &\propto P(z_{\log(y_j)} | z_x, \theta_{0_j}, \theta_{1_j}, \sigma) \cdot P(\theta_{0_j} | \mu_0, \varphi_0, \tau_0, K_j) \cdot P(\theta_{1_j} | \mu_1, \varphi_1, \tau_1, K_j) \cdot \\ &\qquad \qquad P(\sigma) \cdot P(\mu_0) \cdot P(\mu_1) \cdot P(\varphi_0) \cdot P(\varphi_1) \cdot P(\tau_0) \cdot P(\tau_1) \end{split}$$

 K_j and z_x are the outputs and have no priors. The joint posterior over all individuals can then be expressed as:

$$\prod_{j}^{J} P(z_x, K_j, \theta_{0_j}, \theta_{1_j}, \cdots | z_{\log(y_j)}) \propto \prod_{j}^{J} P(z_{\log(y_j)} | z_x, \theta_{0_j}, \theta_{1_j}, \sigma) \cdot P(\theta_{0_j} | \mu_0, \varphi_0, \tau_0, K_j) \cdot P(\theta_{1_j} | \mu_1, \varphi_1, \tau_1, K_j) \cdots$$

A graphical representation of the hierarchical model can be seen in Figure 2.

The **core** of the model is the distribution of the data (i.e. the likelihood function) which models a regression line for each individual with a certain noise around it:

$$\boxed{z_{\log(y_j)} \sim \mathcal{N}(\theta_{0_j} + \theta_{1_j} \cdot z_x, \ \sigma^2)}$$

The assumed shapes of the intermediate priors and pure (hyper-) priors are as follows:

$$\theta_{0_j} \sim \mathcal{N}(\mu_0 + \varphi_0 \cdot K_j, \tau_0^2)$$

$$\theta_{1_j} \sim \mathcal{N}(\mu_1 + \varphi_1 \cdot K_j, \tau_1^2)$$

$$\mu_0, \mu_1, \varphi_0, \varphi_1 \sim \mathcal{U}(-\infty, +\infty)$$

$$\sigma, \tau_0, \tau_1 \sim \mathcal{U} \ |0, +\infty)$$

Note, that the priors in the first line above exclude 0.

Transformations

With the random variables $\Xi, \Theta, \Omega \sim \mathcal{N}(0, 1)$, we can rewrite the distributions as follows:

$$\begin{split} z_{\log(y_j)} &= \theta_{0_j} + \theta_{1_j} \cdot z_x + \sigma \cdot \Xi \\ \theta_{0_j} &= \mu_0 + \varphi_0 \cdot K_j + \tau_0 \cdot \Theta \\ \theta_{1_j} &= \mu_1 + \varphi_1 \cdot K_j + \tau_1 \cdot \Omega \end{split}$$

$$z_{\log(y_i)} = \mu_0 + \varphi_0 \cdot K_j + \tau_0 \cdot \Theta + (\mu_1 + \varphi_1 \cdot K_j + \tau_1 \cdot \Omega) z_x + \sigma \cdot \Xi$$

For the **individual** level, we keep the θ s and do not replace them with their priors:

$$z_{\log(y_j)} = \theta_{0_j} + \theta_{1_j} \cdot \frac{x - \bar{x}}{\hat{\sigma}_x} + \sigma \cdot \Xi$$

$$z_{\log(y_j)} = \theta_{0_j} - \theta_{1_j} \frac{\bar{x}}{\hat{\sigma}_x} + \frac{\theta_{1_j}}{\hat{\sigma}_x} x + \sigma \cdot \Xi$$

$$\log(y_j) = \underbrace{\hat{\sigma}_y \theta_{0_j} - \hat{\sigma}_y \theta_{1_j} \frac{\bar{x}}{\hat{\sigma}_x} + \overline{\log(y_j)}}_{\theta_{0_j, \text{unsc}}} + \underbrace{\hat{\sigma}_y \frac{\theta_{1_j}}{\hat{\sigma}_x}}_{\theta_{1_j, \text{unsc}}} x + \underbrace{\hat{\sigma}_y \sigma}_{\text{unsc}} \cdot \Xi$$

$$\log(y_j) \sim \mathcal{N} \left(\theta_{0_j, \text{unsc}} + \theta_{1_j, \text{unsc}} \cdot x, \ \sigma_{\text{unsc}}^2\right)$$

$$E[y_j] = e^{\theta_{0_j, \text{unsc}} + \theta_{1_j, \text{unsc}} \cdot x + \frac{\sigma_{\text{unsc}}^2}{2}}$$

$$= \underbrace{e^{\theta_{1_j, \text{unsc}} \cdot x}}_{\text{effect of increasing attempts}} e^{\theta_{0_j, \text{unsc}} + \frac{\sigma_{\text{unsc}}^2}{2}}$$

For the **group** level, we can convolute the addition of the random variables Ξ , Θ and Ω assuming independence and merge them into a single one which we call again Ξ :

$$z_{\log(y_j)} = \mu_0 + \varphi_0 \cdot K_j + (\mu_1 + \varphi_1 \cdot K_j)z_x + \sqrt{\sigma^2 + \tau_0^2 + \tau_1^2 z_x^2} \cdot \Xi$$

De-standardising from Equations 1 and 2 yields:

24

$$z_{\log(y_{j})} = \mu_{0} - \mu_{1} \frac{\bar{x}}{\hat{\sigma}_{x}} + \left(\varphi_{0} - \varphi_{1} \frac{\bar{x}}{\hat{\sigma}_{x}}\right) K_{j} + \left(\frac{\mu_{1}}{\hat{\sigma}_{x}} + \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right) x + \sqrt{\sigma^{2} + \tau_{0}^{2} + \tau_{1}^{2} \frac{\bar{x}^{2}}{\hat{\sigma}_{x}^{2}}} - 2 \frac{\tau_{1}^{2} \bar{x}}{\hat{\sigma}_{x}^{2}} x + \frac{\tau_{1}^{2}}{\hat{\sigma}_{x}^{2}} x^{2} \cdot \Xi$$

$$\log(y_{j}) = \underbrace{\hat{\sigma}_{y} \mu_{0} - \hat{\sigma}_{y} \mu_{1} \frac{\bar{x}}{\hat{\sigma}_{x}} + \overline{\log(y_{j})}}_{\mu_{0,\text{unsc}}} + \underbrace{\hat{\sigma}_{y} \left(\varphi_{0} - \varphi_{1} \frac{\bar{x}}{\hat{\sigma}_{x}}\right)}_{\varphi_{0,\text{unsc}}} \cdot K_{j} + \underbrace{\left(\hat{\sigma}_{y} \frac{\mu_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} \cdot K_{j}\right)}_{\varphi_{1,\text{unsc}}} x + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \underbrace{\left(\hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat{\sigma}_{y} \frac{\varphi_{1}}{\hat{\sigma}_{x}} + \hat$$

$$\log(y_j) \sim \mathcal{N}(\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + (\mu_{1,\mathrm{unsc}} + \varphi_{1,\mathrm{unsc}} \cdot K_j)x, \quad \sigma_{\mathrm{unsc}}^2 + \tau_{0,\mathrm{unsc}}^2 + \tilde{\tau}_{1,\mathrm{unsc}}^2 x + \tau_{1,\mathrm{unsc}}^2 x^2)$$

$$E[y_j] = e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + (\mu_{1,\mathrm{unsc}} + \varphi_{1,\mathrm{unsc}} \cdot K_j)x + \frac{\sigma_{\mathrm{unsc}}^2}{2} + \frac{\tau_{0,\mathrm{unsc}}^2}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tau_{1,\mathrm{unsc}}^2 x^2}{2}$$

$$= e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + \frac{\sigma_{\mathrm{unsc}}^2}{2} + \frac{\tau_{0,\mathrm{unsc}}^2}{2} + \frac{\tau_{0,\mathrm{unsc}}^2 \cdot K_j + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tau_{1,\mathrm{unsc}}^2 x^2}{2}}{2}$$

$$= e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + \frac{\sigma_{\mathrm{unsc}}^2}{2} + \frac{\tau_{0,\mathrm{unsc}}^2 \cdot K_j + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x^2}{2}}{2}$$

$$= e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + \frac{\sigma_{\mathrm{unsc}}^2 x}{2} + \frac{\tau_{0,\mathrm{unsc}}^2 \cdot K_j + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x^2}{2}}{2}$$

$$= e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + \frac{\sigma_{\mathrm{unsc}}^2 x}{2} + \frac{\tau_{0,\mathrm{unsc}}^2 \cdot K_j + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x^2}{2}}$$

$$= e^{\mu_{0,\mathrm{unsc}} + \varphi_{0,\mathrm{unsc}} \cdot K_j + \frac{\sigma_{\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{0,\mathrm{unsc}}^2 \cdot K_j + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x}{2} + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^2 x^2}{2} + \frac{\tilde{\tau}_{0,\mathrm{unsc}}^2 x^2}{2} + \frac{\tilde{\tau}_{0,\mathrm{un$$

$$=\underbrace{e^{\varphi_{0,\mathrm{unsc}}\cdot K_{j}}}_{\text{child-effect on "intercept"}} e^{\mu_{0,\mathrm{unsc}} + \frac{\sigma_{\mathrm{unsc}}^{2}}{2} + \frac{\tau_{0,\mathrm{unsc}}^{2}}{2}} \cdot \underbrace{e^{\varphi_{1,\mathrm{unsc}}\cdot K_{j}x}}_{\text{child-effect on "slope"}} e^{\mu_{1,\mathrm{unsc}}x + \frac{\tilde{\tau}_{1,\mathrm{unsc}}^{2}x}{2} + \frac{\tau_{1,\mathrm{unsc}}^{2}x^{2}}{2}}$$

38

40

The multiplicative effect of being a kid acts only on the group level, but the effect of increasing attempts acts on the individual and group level.
